bauer Angular Jasmine's Car Driver's Andron 9.1.0.0.0.jpg Vitamin E, cancer, and human diet.

Epidemiological studies have established a strong inverse association between the intake of vitamin E and the incidence of several common human cancers. This has prompted considerable interest in the mechanisms underlying the potential protective effect of this essential nutrient. This paper reviews the evidence that a relationship between vitamin E and cancer may exist, although it seems unlikely that any single mechanism can account for the protection seen in epidemiological studies. Studies which have examined both vitamin E intake and biochemical markers of antioxidant status are reviewed, as are studies which have explored the role of the antioxidant system in protection against cancer. The majority of human studies indicate that biochemical markers of antioxidant status are positively associated with cancer risk, although only a minority of prospective studies have supported this. An inverse relationship has been observed between plasma vitamin E levels and subsequent cancer risk, although it is uncertain whether this is a consequence of the protection afforded by plasma vitamin E levels or rather an indication of an underlying causal relationship. It is possible that there is no true association between vitamin E and cancer risk but that the positive association observed with markers of antioxidant status reflects a protective effect of high antioxidant status itself, as indicated by prospective studies. However, this is not supported by the negative association seen between plasma vitamin E levels and cancer risk in a majority of studies. It is concluded that further evidence is required before any definitive conclusions can be drawn regarding a relationship between vitamin E and cancer risk. This project aims to test the following hypotheses: 1) Hemorrhage into an inflamed tissue increases the plasma concentration of vasoactive hormones, such as endothelins (ETs), bradykinins (BKs) and substance P (SP), which stimulate the aggregation and permeability of microvascular endothelium. Microvascular leakage of plasma will result in edema formation which may exacerbate the inflammatory response and f988f36e3a
